concentrations in rats, peak levels occur at the end of the light phase, i.e., on the first morning of the phase for nocturnal rodents. In humans, plasma histamine levels increase in the early hours of the morning in healthy volunteers or asthmatic patients. Although still controversial, these nocturnal peaks in steady state plasma histamine levels are implicated in the nighttime exacerbation of asthma symptoms. In any case, there has been little information about the precise mechanisms that regulate plasma histamine levels.

In this study, we have predominantly responsible for maintenance of baseline histamine levels at steady state, and, if so, how this process is influenced by environmental factors.
